AN ACCOUNT

OF

CHRONIC HYDROCEPHALUS.

About the first of May, 1850, a child of Mr. P., of Newburgh, was placed under our care, for the treatment of chronic hydrocephalus. This child was six months of age; its body and extremities were well formed, but the appearance of its head is well represented in Fig. 1st. The circumference of the head was about thirty inches, and, when held between the eye and the light, it was perfectly transparent. The integuments were highly vascular at various points; and at its anterior and posterior portions there were bag-like protuberances, appearing as if about to burst from the pressure of the enormous quantity of fluid within. The health of the child was good, nutrition well performed, and, with the exception of the threatened rupture of the cranial coverings, there were no indications of the mediate danger to life. The head began to enlarge very soon after birth, and continued to increase,

without crying, was deaf, and died without any convulsion or apparent struggle.

These are all the cases we have been able to find, corresponding with our own, as to the almost complete disappearance of the cerebral substance. It certainly is remarkable, that with such extensive disorganization the child should be able to see, hear, taste, feel, &c., and yet this was true not only in my own case but in that of Dr. Wetmore. Transparency of the head, we believe, is not a common feature in this disease, though it has been observed by Butcher (Gazette Médicale, 1843), as well as in the patient which came under our care.

The sudden and spontaneous disappearance of the fluid after diarrhea, copious perspiration, cutaneous eruption, and other salutary crises, has been noticed by M. Nelaton (Elem. de Path. Chirurg., vol. ii., p. 642). Dr. J. W. Hubbell has reported in the New-York Journal of Medicine, May, 1850, p. 396, an interesting case of hydrocephalus terminating spontaneously in recovery, after the appearance of an eruption on the side of the head, which gradually spread over the whole scalp, and kept up a constant and free discharge for the space of two months. The head constantly diminished, while the body increased in size. In two months, the bones of the cranium had approached each other, but not united. In three months, the sutures had united, and the eruption disappeared. The child was fat, and in every respect healthy. -No medication was used at any time. Frank mentions a case which disappeared on the invasion of a scrofulous affection in another part of the body; and both he and Gölis have seen very favorable effects from the appearance of eruptions. In our patient the fluid was transferred to the cellular tissue, covering the whole body.

We have alluded to the perfect manner in which nutrition was performed; and instances are on record in which patients thus affected have reached upwards of thirty years of age. Prof. Vrolik has represented, in his magnificent *Tabulae Embryogennesin Hominis*, &c. (plate 38), the skull taken from a

man, aet. 32, who died affected with internal hydrocephalus. This man "a prima infantia hydrocephalo laboravit, et cum eo ad satis provectam, quam dixi, aetatem pervenit, columnam dorsalem habebat curvatam. Inferioris corporis artus vix superioris pondus sustentare valebant. Ceteroquin erat sanus et nequaquam mente imbecillus." From the uniform and equal distention of the ventricles, this man's head appeared like that of a giant.

Rokitansky states (*Path. Anatomy*, Syd. Ed. vol. iii., p. 366) that, as a general rule, hydrocephalus is a symmetrical disease; and that its chief seat, in all its forms, is the lateral ventricles. When it is found in the arachnoid cavity, according to MM. Rilliet and Barthez (*Traité des Maladies des Enfants*), it is always the result of a hemorrhage from this serous membrane into its cavity; for it is in this variety that the fluid is generally found bloody.

The authors of the Compendium de Chirurgie Pratique, &c., Tome Deuxième, p. 537, remark that it is in these cases we sometimes meet with transparency; but, when seated in the ventricles, the latter, as in the cases related in connection with our own, and likewise by Ruppius, in Meissner's Forschungen, vol. iii., p. 240, may together form one huge cavity; and the cerebral mass around the ventricles, especially towards the top of the head, may, as stated by Rokitansky, and as observed in our own case, be so attenuated as scarcely to measure a line in thickness.

The substance of the brain is often compressed and atrophied, and occasionally it is lacerated at various points. Sometimes it becomes so expanded and so attenuated as to be with difficulty recognized. In some cases, doubtless, there is a close alliance between congenital hydrocephalus and hemicephalus, there being a decided arrest of development in the organum. "I believe," says Rokitansky, "that the really essential part of congenital hydrocephalus—that which arrests the development of the brain—is the affection of the ependyma; that, in proportion to the degree to which the hydrocephalus has advanced, and according to the period

of fœtal life at which it commenced, it does, in various manner, and to different extent, arrest the development of the brain, and occasion monstrosity of it, and so far contains the ground of its alliance with hemicephalus, hydrence-phalocele, singleness of the cerebrum (cyclopia), &c. (Op. cit., p. 363.)

The diagnosis of hydrocephalus, though generally, is not always, unattended with difficulties. For example, in some cases the dimensions of the head, as in the cases observed by Gall, Gölis, Breschet, and Baron, are sometimes less than natural; and then, if the cranium be of unusual size, the latter may be owing to an hypertrophy of the brain. If paracentesis is ever justifiable in cases of hydrocephalus, in hypertrophy of the brain, it can only be productive of mischievous results.* Fig. 2 represents the head of a child some

^{*} Dean Swift, to use his own words,

[&]quot;Gave the little wealth he had

To build a house for fools and mad," &c.

And in this same "house" in Dublin, about a century since, several insane

5 years of age, in which case we were consulted as to the propriety of an operation. From the history of the case, we learned that the head had commenced to grow rapidly shortly after birth, and that the child had never been able to sit or stand erect. Every portion of the cranium was of stony hardness, and with no amount of pressure with the fingers could we produce the slightest indentation. The patient was frequently affected with convulsions and other symptoms of cerebral disturbance, though nutrition was perfect, and the child fat and hearty. He constantly remained in the horizontal position with his head thrown back. Believing the case to be one of hypertrophy, not only of the brain, but of the bones of the cranium, we declined any interference.

In the Brit. For. Med. Chir. Review, April, 1846, we find the following attempt by M. Mauthnier to establish the differential diagnosis of hypertrophy of the brain and chronic hydrocephalus:-

HYPERTROPHY OF THE BRAIN.

1. The posterior part of the skull first presents an unnatural prominence.

2. Children lie horizontally, or throw the head back.

3. Face puffy, eyes inexpressive or staring, mouth half open.

comes on gradually, not before the period of dentition or weaning, and consists at with an expression of premafirst in affection of the respiratory apparatus.

phlegmatic.

CHRONIC HYDROCEPHALUS.

1. The forehead is the first part to present an unnatural prominence; the altered direction of the eyes, and the great width of the sutures, are also characteristic.

2. Children lie on the belly, with the head lower than 4. Functional disturbance the body, and buried in the pillow.

> 3. Countenance etiolated, ture old age.

4. Functional disturbance 5. Patient fat and leuco-begins early, and involves the cerebrum from the beginning.

5. Patient ill nourished, subject to rickets and tabes.

patients were trephined, on the supposition that their insanity was produced by the brain having become too large for the cranium!

In both affections the skull is commonly enlarged, but to the touch the sensation produced by pressure is widely different; in the one giving the idea of a solid, unyielding case. in the other of a wide separation of the bones, which in many cases are but imperfectly ossified. True, even in hypertrophy, where the progress of the disease has been very rapid, the sutures of the skull, in hypertrophy, may become loose and separate, particularly at the upper part of the head, but these cases are rare. Mr. Paget, in his Lectures on Surgical Pathology, Am. Ed., p. 64, remarks that it is very rarely that the due thickness of the skull is attained while its bones are engaged in the extension of their superficial area. "Hence, the weight of an hydrocephalic skull is not much, if at all, greater than that of the healthy one; a large parietal bone (No. 2 in the College Museum), measuring nine inches diagonally, weighs only four ounces, while the weight of an ordinary parietal bone is about three ounces." The extent of the skull, he asserts, is in a measure made up in some of these cases by the symmetrical placing of the wormian bones, thus showing "how the formative process, though thus thrown into straits and difficulties, yet conforms, both in growth and development, with the law of symmetry." This condition of the wormian bones existed in our own patient." Dr. Todd (Cyclop. Anat. and Physiology) observes that it is uncertain what the precise change is which the brain undergoes in hypertrophy, but it is probable that in this perverted nutrition, a new material is deposited between or in the proper anatomical elements of the brain, and that there is evidence of a similar condition of the cranial walls, the bones of the skull being preternaturally thick. The substance of the brain is universally firm, and cuts somewhat like cartilage.

To add to the difficulty connected with the differential diagnosis of chronic hydrocephalus and hypertrophy of the brain, these affections are found sometimes to coexist. Otto, indeed, asserted that hydrocephalus is occasionally cured by the supervention of hypertrophy of the brain, but

upon this point Rokitansky observes (op. cit., p. 359),—"I believe, further, that the hydrocephalus (the hydrocephalic process) may itself sometimes give the first impulse to hypertrophy of the brain; but that any compensation for or cure of hydrocephalus is effected by hypertrophy, appears to be altogether problematical. Such an opinion is founded upon the fact, that in some large skulls of hydrocephalic shape, the brain exceeds the normal size and weight. But I believe that these are cases in which the hypertrophy, having taken place in childhood, has continued ever since; and that belief is confirmed by the resemblance, in shape, which subsists between the skull in hypertrophy and the hydrocephalic skull, as well as by the difficulty which the similarity in the symptoms of hypertrophy and hydrocephalus imposes, upon our determining positively what disease of the brain did exist in childhood. So far as I am aware, the morbid increase in the volume of the brain in hydrocephalus, as well as its normal growth, takes place always in the neighborhood of the enlarged ventricles; it is a peripheral deposition around them; and the skull goes on increasing in size to whatever extent its closure may be prevented by the hydrocephalus."

The skull of Sir Walter Scott was found much thinner than natural after death, and this was supposed to have been caused by cerebral hypertrophy, although the immediate cause of his death was ramollissement of the corpus striatum, producing hemiplegia.

Dr. Forry, the original editor of the New-York Journal of Medicine, died Nov. 24th, 1844, from hypertrophy and induration of the brain. For some months before his death he suffered from epilep-y and other severe cerebral disturbance. The anterior and posterior portions of the skull, corresponding to the hypertrophied cerebral substance, were evidently thinned. Long-continued vascular excitement may lead both to hypertrophy and effusion. Dean Swift, who lived like a madman, and expired "a driveller and a fool," is said to have been temperate in early life, yet, by his

intemperance in after years, he produced the hypertrophy of the brain and the effusion within the cranial cavity which. even at the age of 78, caused his death. Up to 1742, when he was 75 years of age, he showed no symptoms whatever of mental disease, beyond the ordinary decay of nature, nor did he have anything like epileptic attacks or general convulsions until some 36 hours before his death, yet we are informed (Works of Swift, Dub., Faulkner, 1763, vol. ii., p. 261) that Mr. Whiteway, who examined the body, "found much water in the brain." The frontal region of the cranium was thickened, flattened, unusually smooth and hard in some places, whilst in others it was thinned and roughened. At some points in the occipital fossae, the supraorbital plates, &c., the skull was so thin as to be transparent. (Vide Mr. Wilde's Report, &c., Dub. Journ. Med. Science, May and August, 1847.)

Hydrocephalus, therefore, is not a disease confined to any particular age, as is proved by the case reported by Prof. Vrolik, and that of the Dean, just mentioned. Besides these cases, Dr. West refers to another, in which the patient lived to 29 years of age; Dr. Baillie to one of 56 years, whilst Gölis mentions three in which it came on in old age, two of these patients having been upwards of 70 years old. Of course the changes produced upon the skull by chronic hydrocephalus, and hypertrophy of the brain, must vary according to the period of life at which these affections commence. In early life, as in Fig. 2, the cranial bones partake of the hypertrophied action of the brain, and becomes thickened as it expands. In adult life, the effect is different, the bones becoming thinner from the pressure, as seen in the skulls of Sir Walter Scott, Dean Swift, and Dr. Forry. But we have neither time nor space to dwell longer upon this part of the subject, nor could we do so with profit to the reader; for, from among all the writers to which we have been able to refer, we have not succeeded in collecting the elements by which an absolute differential diagnosis in all these cases can be established.

It is not our purpose to discuss the various methods of treatment which have been adopted in chronic hydrocephalus, but shall confine our remarks to puncture of the cranium. The Rev. Mr. Stevens has the credit of being the first to propose trepanning the cranium for hydrocephalus, and this was in the case of Dean Swift, who died in 1745. From Mr. Wilde's report of the Dean's case, to which we have already alluded, we learn that up to 1742, three years before the Dean's death, there were no symptoms of mental disease; and it was not until some 36 hours before his death, that he suffered from epileptic attacks and general convulsions. Conquently we may assume that it was in 1845 that the Rev. Mr. Stephens proposed this operation. Dionis, is his Cours d'Opérations de Chirurgie, 3d ed., 1736, has the following observations:

"Toutes les espèces d'hydrocéphale demandent la main du chirurgien pour donner issue aux eaux qui font la maladie. Les anciens appliquoient deux cautères potentiels, l'un sur le commencement de la suture sagittale, et l'autre sur la pointe de la suture lambdoide; les escarres étant tombées, ils laissent sortir la lymphe par ces deux ouvertures, etc. Je suis plûtot pour les scarifications aux parties déclivés de la tête, par où les eaux, dont elle est abreuvée, peuvent suivre," etc.

He then refers to a case of congenital hydrocephalus, which he cured by this method of treatment. In the *Philosophical Transactions*, vol. xlvii., there is the report of a case in which Le Cat punctured the head for hydrocephalus. The operation was performed on the 23d October, 1744. A trocar with a canula much shorter than ordinary was used. On the upper part of the canula were two circles, each fastened to a different piece, so made as to screw on each other. The circles were somewhat concave on their surfaces, so as reciprocally to correspond, their circumferences touching while there remained a tolerable vacuity towards their centre. A circular piece of plaster, with a hole in its centre, was then applied to the lower circle, the screw of which

passed through the hole of the plaster. The object of this arrangement was to prevent the trocar from penetrating too deeply. The trocar and canula were thrust up to the circles and plaster, which was made adherent to the scalp, after which the trocar was withdrawn, when 4 or 5 ounces of serosity, of a brownish white, "or the color of pale white wine," and somewhat foul, was allowed to issue. This was on the 23d October. On the 24th, he unstopped the canula, and drew off the same quantity. On the 25th, "the infant was ill," for which reason he was not disturbed on that day. On the 26th, he was better, and 5 ounces more were withdrawn. Tuesday he was suffered to rest. Whenever the fluid was withdrawn, the head was bound with a strong bandage. The child died on the night of the 27th. The brain was thin, expanded, in contact with the dura mater, forming a kind of thin sack filled with water. Both lateral ventricles were excessively dilated, and but slight traces of the pineal gland, choroid plexus, remained.

Dr. Remmet, of Plymouth, E., operated in 1778, and 80 ounces of fluid were discharged at five different operations.

The child died on the seventeenth day.

In Van Swieten's Commentaries, vol. xii., p. 248, we find that Petit expressed his regret that all the patients who had been subjected to this operation died. He believed that if a large quantity of water should be drawn off, the patient must die in four or five hours after the discharge; and even if less should be removed, they would still die, though not so speedily, surviving, perhaps, the operation some forty hours, but never longer than this period.

The operation was condemned by Heister, Boerhaave, De la Motte, Paré, Portal, Richter, Gölis, Breschet, Boyer, Dupuytren, Physick. Among the modern opponents of this proceeding we have found none more decided than Dr. Battersby. In his very elaborate paper published in the Edinburgh Medical and Surgical Journal, July, 1850, he has most thoroughly entered into the examination of the pathology of this disease, and he declares that all the evidence

thus far derived from morbid anatomy, as well as from the statistics collected upon the subject, goes to prove that puncture in chronic hydrocephalus is a useless and unjustifiable operation. In abdominal dropsies, as well as in hydrocele of the tunica vaginalis testis, he asserts, the simple withdrawal of the fluid is seldom sufficient to effect a cure; and if, in cases like these, he adds, where the containing parts naturally return to their proper position after the fluid is evacuated, it would be absurd to expect that dropsy of the brain, where the parts cannot reassume their normal position, should be cured by paracentesis of the head. The operation he regards as attended with danger, the cases reported showing that puncture is sometimes followed by an almost immediate aggravation of the cerebral symptoms, and by death. objection urged by him is that the fluid soon collects again. and even if relief be afforded by the first operation, it is less marked in the second, the quantity of fluid even increasing with its repetition. With this increase in the dimensions of the head, the body becomes emaciated; and death takes place from exhaustion, coma, or convulsions. The number of cases in which the operation has been performed is sufficient to settle the question of its value as a curative agent; and, while the statistics bear unfavorably upon it in this light, there can be no question that, as a palliative measure, the surgeon may not unfrequently be justified in resorting to it. Dr. Charles West published in the London Medical Gazette, April, 1842, "An Inquiry into the Results of Puncture of the Head, in cases of Chronic Hydrocephalus," and so completely has he exhausted the subject up to that time, that we are compelled to avail ourselves of his labors. His Table comprises 56 cases, and we have added such as we have been able to find reported since the date of his publication, a period of twelve years.

In relation to the first 16 cases in this table which are reported as successful, (and the same remarks are applicable to the three cases which we have added,) Dr. West very properly observes that chronic hydrocephalus is a disease usually slow in its progress, and intermittent in its advances, occasionally pausing for months, or even years, and then increasing without any evident cause; consequently, before any case be admitted as cured, it must be shown that a considerable time has elapsed since the operation, and that during this period the health of the patient has been perfectly good. The cases which he has collected he regards as affording but little encouragement to resort to it, as might be expected from the appearance frequently presented after death, as in many cases there exists serious organic disease or malformation of the brain itself, "though no symptom during life had betrayed the existence of a condition which mechanical interference could only aggravate."

Dr. Watson, on the other hand, employs very different language in reference to this operation. In his *Lectures*, p. 284, Am. Ed., he remarks: "He must have been a bold physician who first proposed to decant the water from the brain, by means of a perforation, made with a trocar, through the membrane of the fontanelle, through the membranes of the brain, and through even the expanded cerebral substance itself. But the success of the project has amply vindicated

this happy audacity. Though denounced as useless and cruel by some high continental authorities, by Gölis and Richter especially, it furnishes one of the best of the few chances of safety to the patient. Of course, I mean ultimate safety, for the operation itself is attended with the present risk of accelerating the patient's death. We have to consider that, by performing the operation, we incur the danger of abbreviating the existence of a being whose life without it could scarcely be long continued, or capable of enjoyment, but then we afford some chance of a perfect cure. speedy death, or an uncertain life of mental and bodily imbecility, or complete restoration—these are the three events to be looked at. Had I to decide the painful question in reference to one of my own children, I would accept the alternative of probable speedy death on the one hand, or possible complete recovery on the other."

Malgaigne, after examining a great number of facts bearing upon this question, comes to the conclusion: 1st, that the operation may be tried when the patient is from three to four months old, and the disease appears to be stationary; 2d, after this period, when the disease is evidently increasing and threatens the life of the patient. (Bull de Thérapeutique, 1840.)

Dr. Copland observes, "While, therefore, I so far agree

with those who argue for the operation, as to advise it to be tried after the measures I have detailed above have failed, yet I would not recommend its performance early in the disease: 1st, because medical treatment has then sometimes effected a cure, especially when the head has not been very greatly enlarged; and 2dly, because, when the fluid is in the ventricles, as it generally is in cases commencing after birth, a greater depth of brain must be penetrated to reach it at an early than at a later period." (Dictionary of Practical Medicine, vol. i., Am. Ed., p. 779.)

Dr. Charles A. Lee has advised a resort to puncture of the ventricles, even when to effect this object it is necessary to pass the instrument to a great depth. A puncture of the ventricles in cases like our own is not a matter of difficulty, as the distended ventricles formed together one vast cav-

Dr. Joy, in the Cyclopædia of Practical Medicine, vol. ii., Lon. Ed., p. 478, thus expresses his opinion on the subject: "There are a few cases on record where it has appeared to effect a cure, and several where it has palliated the symptoms. In cautious hands, and where only a moderate quantity of water is drawn off at a time, it has rarely been attended with any danger. In cases where all other kinds of treatment have been tried without benefit, this is, perhaps, not altogether to be rejected."

Rilliet and Barthez, Barrier and Legendre sanction the operation only in cases of hydrocephalus arising from sanguineous effusion into the arachnoid cavity, a form of the disease by all authorities admitted to be rare. In cases of acquired chronic hydrocephalus, resulting from a cerebral tumor, or a profound alteration of the brain, they would not recommend it.

Mr. Fergusson regards the operation as worthy of trial, and relates several instances in which it has been performed by himself and his friends. He states that, although his own experience does not enable him to be very sanguine of great success from this proceeding, yet that which has been obtained by others is, in his opinion, a sufficient sanction for a continuance of the practice in all "favorable-looking cases." (*Practical Surgery*, 3d Lon. Ed., p. 556.)

Dieffenbach is strongly opposed to the operation, having, during the earlier part of his professional career, had three unsuccessful cases. Although success may in some few cases have followed it, yet on the whole he is disposed to consider them as fortunate escapes, like those which have been recorded in which a sailor recovered after a ship's anchor had passed through his abdomen, or the shaft of a cabriolet had pierced the thorax of a coachman, &c., &c., upon which cures a surgeon has no right to calculate. (Operative Chirurgie, Zweiter Band, Leipzig. 1848, p. 9.)

Dr. Battersby states that he is acquainted with ten cases in which the operation has been unsuccessfully tried in Dublin, and there can be no doubt that a large number of fatal cases remain, and will ever remain unknown. We have been informed by Prof. Stevens Parker, Dr. Watson, and others in this city, of several cases in which the operation has not averted a fatal termination. Still, we feel persuaded that, in cases similar to our own, and for the end proposed in this case, a surgeon would be justified in resorting to it.

Having thus noticed the sentiments of some of the most prominent authorities as to the propriety of resorting to puncture in chronic hydrocephalus, we would remark, in connection with the cases collected by ourselves and appended to the table of Dr. West, that they do not materially affect the conclusions to which this distinguished physician had arrived. In our own case, the operation was not performed with the expectation of effecting a cure. The very idea of the thing would have been perfectly absurd.

One word as to the proper instrument to be employed in this operation. Dr. Watson states, op. cit., p. 286, that he once requested a surgeon to perform it upon a child, and, to their horror, when the trocar was withdrawn from the canula, "instead of clear serosity, a fine stream of purple blood spouted forth. We naturally thought it was all over with
